

Definition 3.4.6 - Def of Open/Closed Set

Let: $S \subset \mathbb{R}$

if $\text{bd } S \subset S$, then S is closed.

if $\text{bd } S \subset (\mathbb{R} \setminus S)$, then S is open.

Theorem 3.4.7

a. A set S is open iff $S = \text{int } S$; i.e. iff $\forall s \in S$, s is an **interior point**.

b. A set S is closed iff its compliment, $\mathbb{R} \setminus S$ is open.

Equivalently, a set s is open iff $\mathbb{R} \setminus S$ is closed.

Proof.

(a):

→

Assume: S is open

Want to show: $S = \text{int } S$

By definition, $\text{int } S \subset S$.

Want to show: $S \subset \text{int } S$

Let: $x \in S$ (1)

Want to show: $x \in \text{int } S$

Since S is open, $\text{bd } S \subset \mathbb{R} \setminus S$

So, $x \notin \text{bd } S$.

Thus, $\exists \epsilon > 0$ st $N(x, \epsilon) \cap \mathbb{R} \setminus S \neq \emptyset$

$\forall \epsilon > 0$, $N(x, \epsilon) \cap S \neq \emptyset$

$x \in \text{bd } S$ if $\forall \epsilon > 0$,

$N(x, \epsilon) \cap S \neq \emptyset$ and $N(x, \epsilon) \cap (\mathbb{R} \setminus S) \neq \emptyset$

Thus, $N(x, \epsilon) \subset S$.

So, $x \in \text{int } S$.

This proves that $S \subset \text{int } S$

←

Assume: $S = \text{int } S$

Want to show: S is open

Let: $x \in \text{bd } S$

Want to show: $x \in \mathbb{R} \setminus S$

Since $x \in \text{bd } S$, we conclude that $x \notin \text{int } S$.

Side Note

$x \in \text{bd } S$ if, $\forall \epsilon > 0$,

$N(x, \epsilon) \cap S \neq \emptyset$ and $N(x, \epsilon) \cap (\mathbb{R} \setminus S) \neq \emptyset$

Thus, $x \in \mathbb{R} \setminus S$.

So, $\text{bd } S \subset \mathbb{R} \setminus S$.

So, by definition,

S is open.

(b): S is closed iff $\mathbb{R} \setminus S$ is open.

So, $x \notin \text{bd } S$.

Thus, $\exists \epsilon > 0$ st $N(x, \epsilon) \cap S \neq \emptyset$

Hence, $N(x, \epsilon) \subset \mathbb{R} \setminus S$

So, $\mathbb{R} \setminus S$ is open from (a).

←

Assume: $\mathbb{R} \setminus S$ is open

Want to show: S is closed

Let: $x \in \text{bd } S$

Want to show: $x \in S$

Since $x \in \text{bd } S$, $\forall \epsilon > 0$,

$$N(x, \epsilon) \cap S \neq \emptyset \tag{1}$$

and

$$N(x, \epsilon) \cap (\mathbb{R} \setminus S) \neq \emptyset \tag{2}$$

Since $\mathbb{R} \setminus S$ is open, $\forall s \in \mathbb{R} \setminus S$, s is an **interior point** of $\mathbb{R} \setminus S$.

Thus, $x \in S$.

We have shown that $\text{bd } S \subset S$.

By definition, S is closed.

□

Example 3.4.8

a. $[0, 5]$ is a closed set. ($\mathbb{R} \setminus [0, 5] = (-\infty, 0) \cup (5, \infty)$)

b. $(0, 5)$ is an open set.

c. $[0, 5)$ is neither open nor closed.

d. $[2, \infty)$ is a closed set.

e. \mathbb{R} is both open and closed.

$$\text{bd } \mathbb{R} = \emptyset \subset \mathbb{R}$$

$$\text{Also, int } \mathbb{R} = \mathbb{R}$$

Also, \emptyset is both open and closed.

Theorem 2 (not in book)

Let: $x \in \mathbb{R}$, $\epsilon > 0$

Then:

a. $N(x, \epsilon)$ is an open set

b. $N^*(x, \epsilon)$ is an open set

(a)

Proof.

$N(x, \epsilon) = \{y : |y - x| < \epsilon\}$ i.e. $-\epsilon < y - x < \epsilon$

So, $y \in N(x, \epsilon)$ iff $x - \epsilon < y < x + \epsilon$

Let: $y \in N(x, \epsilon)$

We shall find $\hat{\epsilon} > 0$ st

$N(y, \hat{\epsilon}) \subset N(x, \epsilon)$, which will show that

$N(x, \epsilon)$ is open.

Side Note

—(—————)—

x-ep, y-ephat, y, yplusEphat, x, xplusEp

Let: $\hat{\epsilon} = \min \{y - (x - \epsilon), x + \epsilon - y\}$ **(1)**

Want to show: $N(y, \hat{\epsilon}) \subset N(x, \epsilon)$

Let: $z \in N(y, \hat{\epsilon})$

Then, $y - \hat{\epsilon} < z < y + \hat{\epsilon}$ **(2)**

From **(1)**, $\hat{\epsilon} \leq y - (x - \epsilon)$ **(3)**

and

$\hat{\epsilon} \leq x + \epsilon - y$ **(4)**

So from **(4)**,

$y + \hat{\epsilon} \leq y + x + \epsilon - y$

$y + \hat{\epsilon} \leq x + \epsilon$

From **(3)**, $(x - \epsilon) - y \leq -\hat{\epsilon}$ **(5)**

Then,

$y + (x - \epsilon) - y \leq y - \hat{\epsilon}$

$x - \epsilon \leq y - \hat{\epsilon}$ **(6)**

From **(2)**, **(5)**, **(6)**,

$x - \epsilon \leq y - \hat{\epsilon} < z < y + \hat{\epsilon} \leq x + \epsilon$

Therefore,

$x - \epsilon < z < x + \epsilon$

Thus, $z \in N(x, \epsilon)$.

Hence,

$N(y, \hat{\epsilon}) \subset N(x, \epsilon)$

Which proves that

$N(x, \epsilon)$ is open.

(b): $N^*(x, \epsilon)$ is an open set. Similar to **(a)**.

□

Theorem 3.4.10

Let: I be an index set. $I \subset \mathbb{N} \subset \mathbb{R}$

Suppose: $G_\alpha \subset \mathbb{R}$ is an open set $\forall \alpha \in I$

Then,

- a. $\bigcup_{\alpha \in I} G_\alpha$ is an open set.

b. If $G_i \subset \mathbb{R}$ is open $\forall i = 1, 2, \dots, n$ where $n \in \mathbb{N}$

Then $\bigcap_{i=1}^n G_i$ is open.

Proof.

(a):

Let: $x \in \bigcup_{\alpha \in I} G_\alpha$

Thus, $\exists \alpha_0 \in I$ st $x \in G_{\alpha_0}$.

Since G_{α_0} is open, $\exists \epsilon_0 > 0$ st $N(x, \epsilon_0) \subset G_{\alpha_0}$

Thus, $N(x, \epsilon_0) \subset \bigcup_{\alpha \in I} G_\alpha$

This proves that $x \in \text{int}(\bigcup_{\alpha \in I} G_\alpha)$

By Theorem 3.4.7 a),

$\bigcup_{\alpha \in I} G_\alpha$ is open.

(b):

Let: $x \in \bigcap_{i=1}^n G_i$

Thus, $x \in G_i \forall i = 1, 2, \dots, n$

Since G_i is open $\forall i = 1, 2, \dots, n$

$\exists \epsilon_i > 0$ st $N(x, \epsilon_i) \subset G_i \forall i$ from 1 to n.

Choose $\epsilon = \min \{\epsilon_1, \epsilon_2, \dots, \epsilon_n\} > 0$

Then $N(x, \epsilon) \subset N(x, \epsilon_i) \forall i$ from 1 to n.

Hence, $N(x, \epsilon) \subset \bigcap_{i=1}^n G_i$

Hence, $\bigcap_{i=1}^n G_i$ is open. □

Side Note

Corollary 3.4.11

a. Let F_α be closed $\forall \alpha \in I$, I is an index set.

Then $\bigcap_{\alpha \in I} F_\alpha$ is closed.

b. Let F_i be closed $\forall i$ from 1 to n.

Then $(\bigcup_{i=1}^n F_i)$ is closed.

(a):

Notice by de Moivre's theorem:

$$\mathbb{R} \setminus (\bigcap_{\alpha \in I} F_\alpha) = \bigcup_{\alpha \in I} (\mathbb{R} \setminus F_\alpha)$$

Which is open by Theorem 3.4.101 a), since

$\mathbb{R} \setminus F_\alpha$ is open by Theorem 3.4.71 b).

Hence, $\bigcap_{\alpha \in I} F_\alpha$ is closed.

(b): Similar.

Example 3.4.12

Let: $G_n = (\frac{-1}{n}, \frac{1}{n}) \forall n \in \mathbb{N}$

Then $\bigcap_{n=1}^{\infty} G_n = \{0\}$, which is closed.

Compare with Theorem 3.4.101 b):

$(-\infty, 0) \cup (0, -\infty)$

Accumulation (or Limit) Points; Definition 3.4.14

Let: $S \subset \mathbb{R}$

If $\forall \epsilon > 0, N^*(x, \epsilon) \cap S \neq \emptyset$,

Then $x \in \mathbb{R}$ is an **accumulation** or **limit** point.

The set of all accumulation points of S is denoted by S' .

If $x \in S \setminus S'$,

then x is an **isolated point**,

in which case, $\exists \epsilon > 0$ st $N(x, \epsilon) \cap S = \{x\}$

Definition 3.4.16 - Closures

Let: $S \subset \mathbb{R}$

Then the **closure** of S , denoted by $\text{cl } S$, is defined to be:

$\text{cl } S = S \cup S'$

For example:

$S = (0, 1) \cup \{2\}$

$S' = [0, 1]$

$\text{bd } S = \{0, 1, 2\}$
